The study area is located in the Archaeological Complex of Patallacta in Cusco (Perú), within the Eastern Cordillera. The Archeological Complex is located upon the debris landslide, The Incas chose this area to construct a town. To provide security they stabilized the terrain by building a "protection anden" to prevent future landslides. Then they proceeded with the construction of additional terraces along the middle part of the landslide across an area of 8,731 m². In this area, the overload was decreased, which enabled the construction of the town. The entire area was terraced, from the middle to the lower part of the landslide. Because of the specific soil characteristics, they did probably have problems related to displacement of the walls, so that they used transversal mural, which were constructed on top of the foundation up to the middle third part, in order to decrease transversal pressures, to stabilize the andenes, and to prevent displacements.
