The study of the magnetospheric boundary requires the integration of observational data and modelling results. Modelling and analysis tools such as the MIM software package (downloadable from http://www.spaceweather.eu/en/software/mim) can provide uniform access to Cluster and Themis data and to model output. We discuss our experiences with automated caching strategies to speed up remote data access to on-and off-site Cluster and Themis data archives, and with generic data format descriptions to interpret the different storage formats. Such features are especially useful when applying multi-spacecraft data analysis techniques. As an example, we demonstrate how straightforward it is to compute empirical reconstructions of the magnetospheric boundary, be it using Cluster or Themis observations.
