

## **Chemical hindcast experiments using the Unified Model**

M. Parrington and P. Braesicke

Centre for Atmospheric Science, Department of Chemistry, University of Cambridge, UK

Chemical data assimilation provides a tool for exploiting the wealth of data available from satellite instruments such as those on the NASA UARS/EOS and ESA Envisat-1 platforms. A data assimilation scheme, based on a sub-optimal Kalman filter, has been incorporated into a stratospheric version of the Met Office Unified Model with stratospheric chemistry.

In this study, MLS ozone data will be assimilated using this model system. Conducting selected hindcast experiments, we will assess the potential for improving model forecast skill through the assimilation of observed ozone. The model heating rates will be calculated by either using the climatological background ozone (non-interactive) or the assimilated ozone (interactive). By carefully analysing non-interactive and interactive hindcasts, we will be furthering our understanding of chemistry-climate interactions and the mechanisms determining distribution of trace gases in the atmosphere.
