Mass balance of Vatnajökull (1991-2004) and Langjökull (1996-2004) ice caps, Iceland

H. Björnsson, F. Palsson, G. Adalgeirsdottir, S. Gudmundsson Institute of Earth Sciences, University of Iceland, (Contact: hb@raunvis.hi.is)

The mass balance of Vatnajökull ice cap (8175 km^2) has been monitored since 1991 and since 1996 on the Langjökull ice cap (925 km^2) . On Vatnajökull the mass balance was positive from 1991 to 1994, close to zero 1994–1995, but negative since then. Vatnajökull has lost 0.13% of the total ice mass, 4.43 m of water evenly spread over its area, during the entire 14 year survey period. The mass balance for Langjökull was negative after 1996, in total by 10.82 m w.eq., 5.3% of the total ice mass. The mass balance of the ice caps are directly correlated and reflects low winter snow accumulation and high annual temperatures. However, larger variations are seen in the mean specific winter balance of Langjökull than Vatnajökull.
