

Energy-dispersed ions in the PSBL and associated phenomena: Cluster observations

A. Keiling and Collaborators

Space Sciences Laboratory, UC Berkeley, USA

Recent Cluster studies reported properties of multiple energy-dispersed ion structures in the plasma sheet boundary layer at 4-5 Re using for the first time multiple spacecraft. The ion structures showed a complex fine structure with several beamlets. Here we report other particle and field characteristics that were associated with these dispersed ion structures and their sub-structure and that created a rich phenomenology in magnetosphere-ionosphere coupling. The observations suggest a causal relationship between the magnetospheric ion beams, acceleration and heating of outflowing ionospheric ions (H^+ , O^+) and counter-streaming low-energetic electrons, plasma waves, field-aligned currents and Alfvén waves.
